

Performance Test by Jmeter

Result

Here is the casual version for your presentation:
"This is an example of an Apache JMeter Dashboard that I use to run stress tests. It gives me a clear picture of how the system handles heavy workloads.

Key highlights from this report include:

- Performance Statistics: I use this to track response times and transaction throughput, which helps me make sure the system stays stable under pressure.
- Error Analysis: The Errors section is a lifesaver; it helps me pinpoint exactly why failures happen, like in this report, where I identified a specific connection issue.
- Visual Summary: The Requests Summary chart gives me a quick look at the pass/fail ratio for all requests.

Basically, this dashboard is my go-to for checking the system's limits and catching bottlenecks early on

After running the JMeter stress tests, I consolidate all the raw data into this Summary Matrix. Instead of just showing complex technical data, I use this table to make performance tracking clearer and easier to understand.

Here's what I highlight in the matrix :

- Test Parameters: I include details like the number of virtual users (VU), test duration, and ramp-up period to clearly define the workload scenario.
- Performance Metrics: I track the success rate to measure system stability and analyze response times (average, min, and max) to see how the system handles different loads.
- Throughput: This column shows exactly how many transactions the system can handle per second.

“Basically, this matrix acts as my go-to reference to verify if the system meets performance expectations or if there are still bottlenecks that need fixing”
